It has been accepted for inclusion in Volume 12 by an authorized administrator of Washington University Open Scholarship. For more information, please contact digital@wumail.wustl.edu.
Multiple myeloma (MM) accounts for 13% of hematologic cancers and is characterized by a diversity of genetic lesions—translocations, copy number alterations, and single nucleotide variants. We designed a single-platform targeted sequencing approach capable of detecting all three variant types. Here, we focused on the translocations. We performed targeted sequencing of myeloma cells from MM patients (n=96) and detected novel IgH translocations with partners near DERL3 (n=2) and observed outlying expression of DERL3 from RNA-seq data. Since DERL3 regulates protein misfolding, we hypothesized that knockdown of DERL3 in MM would lead to increased apoptosis. After validating the translocation via PCR, we knocked down DERL3 with shRNA constructs in MM cell lines and observed increased cell death in one of two MM cell lines. This study provided some evidence suggesting DERL3 may play a role in regulating MM progression and may be a target of IgH-induced overexpression. Identifying DERL3 as a tumor suppressor gene for MM could lead to increased understanding of MM development and potential use for therapy.
