Using a Partial Order and a Metric to Analyze a Recursive Trace Set Equation

Authors: Jan Tijmen Udding and Tom Verhoeff

In Trace Theory the notion of a process is defined in terms of a set of finite-length traces over an alphabet. These processes are used as the semantics for a program notation. The program text for a recursive component naturally gives rise to an equation over trace sets. This paper takes two approaches at the analysis of that equation. The first approach is based on a partial order and it concentrates on the projection operator for processes. This yields a condition under which the greatest solution of that equation can be approximated by iteration. The second approach introduces a metric on the process domain. Application of Banach's Contraction Theorem results in a condition under which there exists a unique solution that can be approximated by iteration starting anywhere.

Abstract

In Trace Theory the notion of a process is defined in terms of a set of finite-length traces over an alphabet. These processes are used as the semantics for a program notation. The program text for a recursive component naturally gives rise to an equation over trace sets. This paper takes two approaches at the analysis of that equation.

The first approach is based on a partial order and it concentrates on the projection operator for processes. This yields a condition under which the greatest solution of that equation can be approximated by iteration. The second approach introduces a metric on the process domain. Application of Banach’s Contraction Theorem results in a condition under which there exists a unique solution that can be approximated by iteration starting anywhere.

0 The Problem and Its Context

Throughout this paper the reader is assumed to be familiar with the basics of Trace Theory [8,5]. To make the paper self-contained we give a brief summary of the fundamental concepts and notations of Trace Theory in Subsection 0.1. For more details the reader is referred to [5, §1.1–1.3]. General notational conventions are explained in Subsection 0.0. Subsection 0.2 states the recursive equation and the questions about it that inspired the rest of the paper.

In Section 1 we present an overview of two general approaches to recursive equations, viz. based on a partial order and on a metric. A number of statements concerning finiteness of trace sets is collected in Section 2. This section also contains some Trace Theoretic concepts and notations not covered in [5]. It is only needed for the proofs in the succeeding section. Section 3 begins with the definition of the partial order and a summary of earlier results. The major part consists of a detailed investigation of the projection operator. Subsequently the results are applied to the recursive equation. In Section 4, which can be read independently of the preceding two sections, the metric is introduced and analyzed. As an application we strengthen an old theorem about the recursive equation and obtain a new proof for it. Finally, we summarize the results and make suggestions for further research in Section 5.

0.0 General Notational Conventions

We use a slightly unconventional notation for variable-binding constructs. For example, universal quantification is denoted by

\[(\forall l : D : E),\]

where \(\forall\) is the quantifier, \(l\) is a list of bound variables, \(D\) is a predicate, and \(E\) is the quantified expression. Both \(D\) and \(E\) will, in general, contain variables from \(l\). Predicate \(D\) determines the domain over which the bound variables range. Expression \(E\) need only be defined for values that satisfy \(D\).

Existential quantification is denoted likewise using the quantifier \(\exists\). The quantifier for set construction is implicit in the braces. For instance,

\[\{i : i \geq 0 : i^3\}\]

is the set of cubes. Numbers are implicitly restricted to the set of natural numbers unless stated otherwise.
A sequence in set $D$ is a mapping from the natural numbers into $D$. Function application is in this case often denoted by sub-scripting. If $F$ is, for example, the sequence of Fibonacci numbers then

$$F_{n+2} = F_{n+1} + F_n$$

for $n \geq 0$.

For expressions $E$ and $G$, an expression of the form $E \Rightarrow G$ will often be proved in a number of steps by the introduction of intermediate expressions. For instance, we can prove $E \Rightarrow G$ by proving $E \equiv F$ and $F \Rightarrow G$ for some expression $F$. In order not to be forced to write down expressions like $F$ twice, we record proofs like these as follows.

$$E$$

= \{ \text{hint why } E \equiv F \} \setminus F$$

$\Rightarrow$ \{ hint why $F \Rightarrow G$ \} \setminus G$

0.1 Trace Theory

Let $\Omega$ be a (possibly infinite) set; its elements are called symbols. An alphabet is a subset of $\Omega$. For alphabet $A$ the set of finite-length sequences over $A$ is denoted by $A^*$. Elements of $\Omega^*$ are called traces. A trace set is a set of traces. The length of trace $t$ is denoted by $\ell(t)$. The empty trace is denoted by $\epsilon$, and concatenation of traces is denoted by juxtaposition.

Trace $t$ is prefix of trace $u$, denoted by $t \leq u$, when ($\exists v : v \in \Omega^* : tv = u$). The prefix-closure of trace set $V$, denoted by $\text{pref}(V)$, is the trace set defined by

$$\text{pref}(V) = \{ t, v : t \leq u \land v \in V : t \}.$$  

Trace set $V$ is prefix-closed when $\text{pref}(V) = V$. Trace $t$ projected on alphabet $A$ is the trace denoted by $t[A]$ obtained from $t$ by deleting all occurrences of symbols not in $A$. That is, for trace $t$, symbol $a$, and alphabet $A$ we have

$$\epsilon[A] = \epsilon$$

$$ta[A] = (t[A])a \text{ if } a \in A$$

$$ta[A] = t[A] \text{ if } a \notin A$$
A process is a pair \( \langle A, V \rangle \) where \( A \) is some alphabet and \( V \) is a non-empty prefix-closed trace set with \( V \subseteq A^* \). For process \( T \) its alphabet is also denoted by \( aT \) and its trace set by \( tT \). As a slight abuse of notation we shall sometimes write \( t \in T \) for \( t \in tT \). The collection of processes with alphabet \( A \) is denoted by \( T(A) \).

The weave of processes \( T \) and \( U \) is the process denoted by \( TwU \) and defined by

\[
TwU = \langle aT \cup aU, \{ t : t \in (aT \cup aU)^* \land t[aT \in T \land t[aU \in U : t] \}. 
\]

Weaving models parallel composition where interaction by means of the common symbols is symmetric and synchronous. The projection of process \( T \) on alphabet \( A \) is the process denoted by \( T[\cdot]A \) and defined by

\[
T[\cdot]A = \langle aT \cap A, \{ t : t \in T : t[\cdot]A \}. 
\]

Projection models abstraction of (internal) communications.

A renaming \( p \) of alphabet \( A \) is a one-to-one mapping from \( A \) into \( \Omega \) such that

\[
(\forall a : a \in A : p \cdot a \notin A).
\]

A renaming is extended (where its domain permits) to operate on alphabets, traces, trace sets, and processes in the obvious way. Function application for renamings is written with a dot, i.e. \( p \cdot a \) for \( p(a) \). For example, for renaming \( p \) of alphabet \( A \) we have

\[
p \cdot A = \{ a : a \in A : p \cdot a \}
\]

and, hence, \( A \) and \( p \cdot A \) are disjoint alphabets.

0.2 The Equation

The processes of Trace Theory serve as the semantics of a program notation [5, Ch. 2]. The semantic function that maps a program text onto its associated process will be denoted by \( PR \) ([5] uses \( TR \)). Instead of giving a complete definition of the program notation’s syntax and the semantic function \( PR \) we present just enough to describe the problem studied in this paper.

The simplest form of program text is a regular expression over \( \Omega \) (excluding \( \emptyset \)), which is also called a command. The meaning of command \( B \) is defined by
\[ PR(E) = \langle A, \text{pref}(\mathcal{L}(E)) \rangle, \]

where \( A \) is the set of symbols that occur in \( E \) and \( \mathcal{L}(E) \) is the language (trace set) generated by \( E \). We use the following operators in regular expressions (in order of increasing binding power): \text{bar} (\|) for union, \text{semicolon} (;) for concatenation, and \text{asterisk} (*) for Kleene closure. For example, we have

\[ PR(a \mid b ; c^*) = \langle \{a, b, c\}, \{e, a\} \cup \{i : i \geq 0 : b(c^i)\} \rangle. \]

Process \( R \) is regular when there exists a command \( E \) such that \( R = PR(E) \).

A more complex program text, also called component, combines: a process defined previously by some other program text, \( \varepsilon \) renaming, and a command. The exact syntax of components does not concern us here. We are interested in the way that the meaning of such a component is defined in terms of its three parts. Consider component \( c \) consisting of: previously defined component \( d \), renaming \( p \) of \( aPR(d) \), and command \( E \) with \( p \cdot aPR(d) \subseteq aPR(E) \). The meaning of \( c \) is defined by

\[ PR(c) = (PR(E) \sqcup p \cdot PR(d))[A], \]

where alphabet \( A \) equals \( aPR(E) \setminus p \cdot aPR(d) \). The idea is that in component \( c \) processes \( PR(E) \) and \( PR(d) \) operate in parallel, being connected according to \( p \). Alphabet \( A \) gives the external communications of \( c \) (\( aPR(c) = A \)) and all communications with \( PR(d) \) are internal. The latter means that \( PR(d) \) is a local process of \( c \); \( d \) is, therefore, called the subcomponent of \( c \). The way the meaning of \( c \) is obtained from its constituents resembles the master/slave operator of [7].

Now imagine that we attempt to define a recursive component \( c \) that has itself as subcomponent, by requiring for subcomponent \( d \) that it has the same meaning as \( c \), that is, \( PR(d) = PR(c) \). The equation defining the meaning of \( c \) then becomes

\[ PR(c) = (PR(E) \sqcup p \cdot PR(c))[A]. \tag{0} \]

There are a number of questions to be asked about this equation if it is to serve as a definition for the meaning of recursive components. Does the equation have a solution for \( PR(c) \)? Is there, possibly, more than one solution? If the solution is not unique, can we easily single out a specific (canonical) solution? Can we prove things about the canonical solution? Can the canonical solution be “implemented”? Can the canonical solution, for instance, be captured explicitly in a closed formula, maybe as some limit of “manageable” (finite, regular) approximations?
These are the questions that inspired this paper. We shall deal with a generalization of recursive equation (0). We do not restrict ourselves to regular processes in the role of PR(E). Hence, we get the following problem formulation. Given alphabet A, renaming p of A, and process R in T(A U p·A) analyze the recursive equation

\[ S = (R w p·S) [A] \]  

(1)

for processes S in T(A). Since (1) is trivially satisfied as far as the alphabets of the processes are concerned, the problem can also be cast in a trace set form: Given alphabet A, renaming p of A, and trace set R with \( R \subseteq (A U p·A)^* \) analyze the recursive trace set equation

\[ S = \{ t : t \in R \land t[p·A \in p·S : t[A] \} \]

for trace sets S with \( S \subseteq A^* \).

1 Two Approaches to Recursive Equations

Let us generalize equation (1) even further. Define the function f from T(A) into T(A) by

\[ f(S) = (R w p·S) [A]. \]

(2)

Equation (1) can now be rephrased as

\[ f(S) = S, \]

that is, we are interested in fixed points of this function f.

Even more abstractly, suppose we have some set D and a function f from D into D. We are interested in the equation \( x : f(x) = x \) over D, i.e. in fixed points of f. We give an overview of two ways in which further knowledge about D and f can be helpful to analyze this equation.

1.0 Complete Partial Orders (CPOs)

For the first approach it is necessary to find a partial order \( \sqsubseteq \) on D, that is, a reflexive, antisymmetric, and transitive relation \( \sqsubseteq \) on D. The structure \((D, \sqsubseteq)\) is then called a poset.

Let us assume we have found such a relation \( \sqsubseteq \) on D. This gives rise to the following notions for a subset X of D:
1 TWO APPROACHES TO RECURSIVE EQUATIONS

- least element of $X$,
- upper bound of $X$,
- least upper bound of $X$, and
- $X$ is a chain.

We assume that the reader is familiar with the first three notions (cf. [1]).
If $X$, $X \subseteq \mathcal{D}$, has a least upper bound in $\mathcal{D}$ then this least upper bound is denoted by $\bigsqcup X$. A chain is a subset of $\mathcal{D}$ on which $\subseteq$ induces a linear order. We call a poset complete, or a CPO, when every chain has a least upper bound in $\mathcal{D}$. Notice that $\emptyset$ is a chain and that $\bigsqcup \emptyset$ is the least element of the CPO; it is called bottom and denoted by $\bot$.

The above notions for subsets are extended to sequences by applying them to the subset $\{n : n \geq 0 : S_n\}$ for sequence $S$ in $\mathcal{D}$. Sequence $S$ in $\mathcal{D}$ is called ascending when $S_n \subseteq S_{n+1}$ for all $n \geq 0$. Notice that in this case the set $\{n : n \geq 0 : S_n\}$ is a chain in $\mathcal{D}$.

Function $f : \mathcal{D} \rightarrow \mathcal{D}$ is monotonic on the poset when $x \subseteq y$ implies $f(x) \subseteq f(y)$ for every $x$ and $y$ in $\mathcal{D}$. Moreover, we call function $f$ upward continuous when for every ascending sequence $S$ in $\mathcal{D}$ that has a least upper bound, the least upper bound of $\{n : n \geq 0 : f(S_n)\}$ exists and

$$f(\bigsqcup \{n : n \geq 0 : S_n\}) = \bigsqcup \{n : n \geq 0 : f(S_n)\}$$

Abian–Brown's Fixed Point Theorem [0, Thm. 2] implies that a monotonic function on a CPO has a (unique) least fixed point. Furthermore, if $f$ is upward continuous, then its least fixed point is

$$\bigsqcup \{n : n \geq 0 : f^n(\bot)\},$$

where $f^n$ denotes the function $f$ iterated $n$ times.

Thus, if we can find a relation $\sqsubseteq$ on $\mathcal{D}$ such that $(\mathcal{D}, \sqsubseteq)$ is a CPO and $f$ is monotonic on this CPO, then the equation $x : f(x) = x$ has a (unique) least solution in $\mathcal{D}$. If $f$ is also upward continuous, then this least solution can be approximated by iteration of $f$ starting in $\bot$.

In the literature there is little agreement on the terminology regarding posets. Especially, completeness and continuity have been defined in many ways, often yielding subtly different concepts. When choosing between alternative definitions one faces three conflicting interests: the complexity of the concepts, their range of application, and the complexity of proofs about fixed points. Our choice yields fairly simple definitions for completeness and
continuity with wide applicability, but the proof for the existence of a least fixed point is complicated (it needs to be done only once, of course). The reader may wish to consult [6] for some pointers into the literature.

The dual of relation \(\sqsubseteq\) on \(\mathcal{D}\) is the relation \(\sqsupseteq\) defined by

\[ x \sqsupseteq y \equiv y \sqsubseteq x \]

for all \(x\) and \(y\) in \(\mathcal{D}\). Notice that the dual of \(\sqsupseteq\) is again \(\sqsubseteq\). The dual of a notion defined in the context of the structure \((\mathcal{D}, \sqsubseteq)\) is that same notion but now placed in the context of the dual structure \((\mathcal{D}, \sqsupseteq)\). Table 0 lists pairs of notions that are dual. Notice that poset, chain, and monotonic are self-dual, but CPO is not. We may thus go back and forth between dual structures or we may stick with one and consider dual notions instead. We have preferred the latter, which explains why Subsection 3.1 is about descending sequences even though they have not been mentioned so far.

Table 0: Dual notions

Even if one is only interested in functions from a poset into itself, then it may still be useful to generalize the notions of monotonicity and continuity to functions from one poset into another. The reason is that function composition maintains monotonicity and continuity. Thus monotonicity of a function from a poset into itself can be proven by decomposing it into a number of simpler functions mapping into (possibly) different intermediate posets and proving their monotonicity separately.

For example, if \((\mathcal{D}_0, \sqsubseteq_0)\) and \((\mathcal{D}_1, \sqsubseteq_1)\) are posets, then \(f: \mathcal{D}_0 \to \mathcal{D}_1\) is called monotonic when
\( x \subseteq y \Rightarrow f(x) \subseteq f(y) \)

for all \( x \) and \( y \) in \( D_0 \). If \( g : D_1 \to D_0 \) is also a monotonic function, then \( g \circ f \) maps \( D_0 \) monotonically into itself. The definitions of upward (and downward) continuity are extended in a similar way.

1.1 Complete Metric Spaces (CMSs)

In the second approach one needs to find a metric \( d \) on \( D \), that is, a function \( d : D \times D \to \mathcal{R} \), where \( \mathcal{R} \) is the set of real numbers, such that for all \( x, y, \) and \( z \) in \( D \):

0. \( d(x, y) \geq 0 \),
1. \( d(x, y) = 0 \iff x = y \),
2. \( d(x, y) = d(y, x) \), and
3. \( d(x, y) \leq d(x, z) + d(z, y) \).

The structure \( (D, d) \) is then called a metric space.

Let us assume that \( d \) is a metric on \( D \). This gives rise to the following notions for a sequence \( S \) in \( D \):

- limit of \( S \), and

- \( S \) is a Cauchy sequence.

We assume that the reader is familiar with the first notion (cf. [4]). Sequence \( S \) is a Cauchy sequence when

\[
(\forall \epsilon > 0 : (\exists N : (\forall m, n : m \geq N \land n \geq N : d(S_m, S_n) < \epsilon)),
\]

where \( \epsilon \) ranges over the real numbers. A metric space is called complete, or a CMS, when every Cauchy sequence has a limit in \( D \).

Function \( f : D \to D \) is a contraction on the metric space when there exists a real number \( c, 0 \leq c < 1 \), such that

\[
d(f(x), f(y)) \leq c \cdot d(x, y)
\]

for all \( x \) and \( y \) in \( D \). Banach's Contraction Theorem states that a contraction on a CMS has a unique fixed point and that for every \( x \) in \( D \) this fixed point equals the limit of the sequence \( S \) defined by \( S_n = f^n(x) \).

Thus, if we can find a metric \( d \) on \( D \) such that \( (D, d) \) is a CMS and \( f \) is a contraction on this CMS, then the equation \( x : f(x) = x \) has a unique solution in \( D \) and it can be approximated by iteration of \( f \) starting anywhere in \( D \).
2 Finiteness of Trace Sets

In this section we have collected a number of statements concerning the finiteness of trace sets.

We write $\#V$ for the number of elements in set $V$. "Set $V$ is finite" will also be expressed by the formula $\#V < \infty$. The length of trace set $V$ is denoted by $\ell(V)$ and is defined by

$$\ell(\emptyset) = 0,$$
$$\ell(V) = (\max t : t \in V : \ell(t) + 1), \text{ for } V \neq \emptyset.$$ 

Trace set $V$ is called bounded when $\ell(V) < \infty$. Because traces have finite length, we obviously have

**Property 0** For trace set $V$

$$\#V < \infty \Rightarrow \ell(V) < \infty,$$

that is, a finite trace set is bounded.

Furthermore, $\ell(t) < \ell(V)$ for every trace $t \in V$. Since $s \leq t$ implies $\ell(s) \leq \ell(t)$, we also see that $\ell(\text{pref}(V)) = \ell(V)$.

**Property 1** For trace set $V$

$$\#V < \infty \equiv \#\text{pref}(V) < \infty,$$

that is, a trace set is finite if and only if its prefix-closure is finite.

**Proof** Observe that $V \subseteq \text{pref}(V)$ and that the number of prefixes of trace $t$ equals $\ell(t) + 1$. Therefore, we have

$$\#V \leq \#\text{pref}(V) \leq \#V * \ell(V).$$

Finally, recall Property 0.

(End of Proof)

For trace set $V$ and integer $k$, $k \geq 0$, the $k$-th level of $V$ is the trace set denoted by $V^{[k]}$ and defined by

$$V^{[k]} = \{ t : t \in V \land \ell(t) = k : t \}.$$ 

Trace set $V$ is called level-finite when all its levels are finite.

**Property 2** If trace set $V$ is bounded, then
\[ \#V < \infty \equiv (\forall k : k \geq 0 : \#V^{[k]} < \infty), \]

that is, a bounded trace set is finite if and only if it is level-finite.

**Proof** Observe that

\[ V = (\bigcup k : 0 \leq k < \ell(V) : V^{[k]}). \]

(End of Proof)

**Property 3** Prefix-closed trace set \( V \) is bounded if and only if

\[ (\exists k : k \geq 0 : V^{[k]} = \emptyset). \]

**Proof** Let \( V \) be a prefix-closed trace set. If \( V \) is bounded, then taking \( k = \ell(V) \) will do. Now assume that \( V^{[k]} \) is empty for some \( k \geq 0 \). Since \( V \) is prefix-closed, \( V^{[n]} \) is empty for all \( n \geq k \) as well. Hence, \( V \) is bounded.

(End of Proof)

Trace set \( V \) has *finite fanout*, denoted by \( \text{finfan}(V) \), when

\[ (\forall t : t \in V : \# \{ a : a \in \Omega \land ta \in V : ta \} < \infty). \]

Obviously, a finite trace set has finite fanout.

**Property 4** Prefix-closed trace set \( V \) has finite fanout if and only if it is level-finite.

**Proof** For the if-part observe that for trace \( t \in V \)

\[ \# \{ a : a \in \Omega \land ta \in V : ta \} \leq \#V^{[\ell(t)+1]} . \]

The only-if-part follows by mathematical induction on \( k \): \( \#V^{[0]} \leq 1 \), and for \( k \geq 0 \)

\[ V^{[k+1]} = (\bigcup t : t \in V^{[k]} : \{ a : a \in \Omega \land ta \in V : ta \}), \]

because of the prefix-closedness of \( V \).

(End of Proof)

**Lemma 0** For prefix-closed trace set \( V \)

\[ \ell(V) < \infty \land \text{finfan}(V) \Rightarrow \#V < \infty, \]

that is, a bounded prefix-closed trace set with finite fancut is finite.
**Proof** Use Properties 2 and 4.

(End of Proof)

**Property 5** For trace set $V$ and alphabets $A$ and $B$ such that $V \subseteq A^*$ and $A \setminus B$ is finite

$$\text{finfan}(V[B]) \Rightarrow \text{finfan}(V).$$

**Proof** Observe that on account of $V \subseteq A^*$ we have for trace $t \in V$

$$\{a : a \in \Omega \land ta \in V : a\} \subseteq \{a : a \in \Omega \land (t[B])a \in (V[B]) : a\} \cup (A \setminus B).$$

(End of Proof)

It may be interesting to observe that, in general, the reverse implication does not hold in the above property.

**Lemma 1** For trace set $V$ and alphabets $A$ and $B$ such that $V \subseteq A^*$ and $A \setminus B$ is finite

$$\ell(V) < \infty \land \#(V[B]) < \infty \Rightarrow \#V < \infty.$$

**Proof** Let $A$ and $B$ be alphabets with $A \setminus B$ finite, and let $V$ be a trace set with $V \subseteq A^*$. We derive

$$\ell(V) < \infty \land \#(V[B]) < \infty$$

$$= \{ \ell(V) = \ell(\text{pref}(V)) \text{ and Property 1} \}$$

$$\ell(\text{pref}(V)) < \infty \land \#\text{pref}(V[B]) < \infty$$

$$= \{ \text{pref}(V[B]) = \text{pref}(V)[B] \}$$

$$\ell(\text{pref}(V)) < \infty \land \#(\text{pref}(V)[B]) < \infty$$

$$\Rightarrow \{ \text{a finite trace set has finite fanout} \}$$

$$\ell(\text{pref}(V)) < \infty \land \text{finfan}(\text{pref}(V)[B])$$

$$\Rightarrow \{ \text{Property 5, using finiteness of } A \setminus B \}$$

$$\ell(\text{pref}(V)) < \infty \land \text{finfan}(\text{pref}(V))$$

$$\Rightarrow \{ \text{Lemma 0 applied to } \text{pref}(V) \}$$

$$\#\text{pref}(V) < \infty$$

$$= \{ \text{Property 1} \}$$

$$\#V < \infty$$
(End of Proof)

The following two lemmas deal with descending sequences of trace sets. Sequence $V$ is descending when $V_{n+1} \subseteq V_n$ for all $n \geq 0$. Since the poset $(\mathcal{P}(X), \subseteq)$ is well-founded—that is, every non-empty chain in it has a least element—if (and only if) $X$ is a finite set, we have

**Lemma 2** If $V$ is a descending sequence of finite trace sets, then

$$\exists i : i \geq 0 : (\bigcap n : n \geq 0 : V_n) = V_i,$$

and, thus

$$\bigcap n : n \geq 0 : V_n = \emptyset \equiv (\exists n : n \geq 0 : V_n = \emptyset).$$

**Lemma 3** If $V$ is a descending sequence of prefix-closed trace sets such that all $V_n$ are level-finite, then

$$\#(\bigcap n : n \geq 0 : V_n) < \infty \equiv (\exists n : n \geq 0 : \# V_n < \infty).$$

**Proof** Define $V_\omega$ as $(\bigcap n : n \geq 0 : V_n)$. Observe that $V_\omega$ is prefix-closed and that

$$V_\omega^{[k]} = (\bigcap n : n \geq 0 : V_n^{[k]}).$$

Hence, all $V_n^{[k]}$ are finite. We now derive

$$\# V_\omega < \infty$$

$$= \{ \text{Properties 0 and } 2, \text{ using the finiteness of } V_\omega^{[k]} \}$$

$$\ell(V_\omega) < \infty$$

$$= \{ \text{Property } 3, \text{ using the prefix-closedness of } V_\omega \}$$

$$= \{ \text{ above observation } \}$$

$$= \{ \exists k : k \geq 0 : V_\omega^{[k]} = \emptyset \}$$

$$= \{ \text{Lemma 2, using the finiteness of } V_\omega^{[k]} \}$$

$$= \{ \exists k : k \geq 0 : (\exists n : n \geq 0 : V_n^{[k]} = \emptyset) \}$$

$$= \{ \text{ predicate calculus } \}$$

$$= \{ \exists n : n \geq 0 : (\exists k : k \geq 0 : V_n^{[k]} = \emptyset) \}$$

$$= \{ \text{ Property } 3, \text{ using the prefix-closedness of } V_n \}$$

$$= \{ \exists n : n \geq 0 : \ell(V_n) < \infty \}$$

$$= \{ \text{ Properties 0 and } 2, \text{ using the finiteness of } V_n^{[k]} \}$$

$$= \{ \exists n : n \geq 0 : \# V_n < \infty \}$$

(End of Proof)
3 The CPO Approach

In Subsection 3.0 a partial order on processes is defined, viz. based on the subset ordering of their trace sets. We briefly summarize earlier results for this partial order; for example, it is complete. Subsection 3.1 analyzes the projection operator with regard to descending sequences of processes. We characterize a subset of the process domain on which projection is downward continuous. Finally, Subsection 3.2 derives an approximation theorem for the greatest solution of equation (1).

3.0 The Partial Order and Some Earlier Results

For more details on the material of this subsection the reader is referred to [5, §1.6].

We define the relation $\subseteq$ on the process domain by

$$ T \subseteq U \equiv aT = aU \land tT = tU $$

for all processes $T$ and $U$. The relation $\subseteq$ is a partial order.

Let $A$ be an alphabet. We denote the relation that $\subseteq$ induces in $T(A)$ by the same name. The structure $\langle T(A), \subseteq \rangle$ is a poset. It has bottom and top, viz. the processes $STOP(A)$ and $RUN(A)$ respectively, defined by

$$ STOP(A) = \langle A, \{\varepsilon\} \rangle, $$

$$ RUN(A) = \langle A, A^* \rangle. $$

Least upper bound and greatest lower bound exist for every subset $X$ of $T(A)$, viz.

$$ (\bigcup T : T \in X : T) = \left\{ \begin{array}{ll} STOP(A) & \text{if } X = \emptyset \\
A, (\bigcup T : T \in X : tT) & \text{if } X \neq \emptyset \end{array} \right. $$

and

$$ (\bigcap T : T \in X : T) = \left\{ \begin{array}{ll} RUN(A) & \text{if } X = \emptyset \\
A, (\bigcap T : T \in X : tT) & \text{if } X \neq \emptyset \end{array} \right. $$

respectively. This makes $\langle T(A), \subseteq \rangle$ and its dual CPOs. (In fact, they are even complete lattices.)

Weaving with a fixed process and renaming are upward and downward continuous, and hence monotonic. Projection is upward continuous, and
hence also monotonic. Since the function \( f \) defined by (2) is the composition of upward continuous functions it is itself upward continuous, and thus monotonic. Application of the Fixed Point Theorem then tells us that \( f \) has a least and a greatest fixed points. Furthermore, from the upward continuity of \( f \) we infer that the least fixed point of \( f \) is, in fact,

\[
(\bigcup n : n \geq 0 : f^n(\text{STOP}(A))).
\]

The following "standard" counterexample shows that, in general, projection is not downward continuous.

**Example 0** Define sequence \( T \) by

\[
T_n = \langle \{a, b\}, \text{pref}\{i : i \geq n : a^i b\}\rangle
\]

and take \( B = \{b\} \). Then we have:

\[
T_\omega = \langle \{a, b\}, \{i : i \geq 0 : a^i\}\rangle
\]

\[
T_\omega[B] = \langle \{b\}, \{\varepsilon\}\rangle
\]

\[
T_n[B] = \langle \{b\}, \{\varepsilon, b\}\rangle \quad \text{for } n \geq 0
\]

\[
(\bigcap n : n \geq 0 : T_n[B]) = \langle \{b\}, \{\varepsilon, b\}\rangle
\]

Hence, \( T_\omega[B] \neq (\bigcap n : n \geq 0 : T_n[B]) \).

(End of Example)

Because projection is not downward continuous, we cannot infer an approximation result for the greatest fixed point of \( f \). That, in general, the greatest fixed point of function \( f \) is not

\[
(\bigcap n : n \geq 0 : f^n(\text{RUN}(A))),
\]

is shown by the next example (cf. the example following Thm. 3.0 in [9]).

**Example 1** Define alphabet \( A \) as \( \{a, b\} \) and define process \( U \) by

\[
U = \langle A \cup p \cdot A, \text{pref}\{i : i \geq 0 : (p \cdot a)^i (p \cdot b) a^{i+1} b\}\rangle.
\]

For \( n \geq 1 \) we now have

\[
f^n(\text{RUN}(A)) = \langle A, \text{pref}\{i : i \geq n : a^i b\}\rangle
\]

and, thus,

\[
(\bigcap n : n \geq 0 : f^n(\text{RUN}(A))) = \langle A, \{i : i \geq 0 : a^i\}\rangle.
\]
3.1 Projection and Descending Sequences of Processes

This is not a fixed point since applying \( f \) once more yields \( \text{STOP}(A) \), which turns out to be the unique fixed point of \( f \).

Notice that the sequence of approximations \( f^n(\text{RUN}(A)) \) is the same as the sequence \( T \) from Example 0.

(End of Example)

In the preceding example \( U \) is not a regular process. The following example is based on a regular process \( U \).

Example 2 Consider alphabet \( A = \{a, b, c\} \) and process \( U \) defined by

\[
U = PR((a; p\cdot a)^*; a; p\cdot b; b | (p\cdot a)^*; p\cdot b; c).
\]

For \( n \geq 1 \) we have

\[
f^n(\text{RUN}(A)) = PR(a^n; a^n; b | c).
\]

Thus

\[
(\bigcap n : n \geq 0 : f^n(\text{RUN}(A))) = \langle A, \{i : i \geq 0 : a^i\} \cup \{c\} \rangle,
\]

which is not a fixed point. Applying \( f \) once more yields the (unique) fixed point \( \langle A, \{i : i \geq 0 : a^i\} \rangle \).

The process can be slightly modified to reduce the size of the alphabet by taking alphabet \( A = \{a, b\} \) and

\[
U = PR((a; p\cdot a)^*; a; p\cdot b; b | (p\cdot a)^*; p\cdot a; p\cdot b; b).
\]

(End of Example)

3.1 Projection and Descending Sequences of Processes

In this subsection we investigate distribution of projection over the intersection (greatest lower bound) of descending sequences, because that will give a clearer picture of why projection is not downward continuous.

In this subsection \( A \) is an alphabet, \( T \) is a descending sequence in \( \mathcal{T}(A) \), and \( B, B \subseteq A \), is an alphabet such that \( A \setminus B \) is finite. The process \( T_\omega \) is defined as \( (\bigcap n : n \geq 0 : T_n) \). From

\[
\text{true} = \{ T_\omega \text{ is a lower bound of the sequence } T \}
\]

\[
(\forall n : n \geq 0 : T_\omega \subseteq T_n)
\]
\[ \Rightarrow \{ \text{projection is monotonic}\} \]
\[(\forall n : n \geq 0 : T_\omega[B \subseteq T_n[B)] \]
\[= \{ \text{property of greatest lower bound}\} \]
\[T_\omega[B \subseteq (\bigcap n : n \geq 0 : T_n[B)] \]

we infer
\[(\bigcap n : n \geq 0 : T_n)[B \subseteq (\bigcap n : n \geq 0 : T_n[B)]. \quad (5)\]

We are interested in conditions under which equality holds in (5). We shall formulate one necessary and sufficient condition and three sufficient conditions for equality in (5). This will also enable us to find a condition under which (4) does yield the greatest fixed point.

We now introduce some auxiliary concepts. For trace \(u\), process \(T\), and alphabet \(C\), the trace set \(\text{orig}(u,T,C)\) is defined by
\[\text{orig}(u,T,C) = \{t : t \in T \land t[C = u : t]\}.\]

Obvious properties of \(\text{orig}\) are:
\[\text{orig}(u,T,C)[C \subseteq \{u\}, \quad (6)\]
\[\text{orig}(u,T,C) \neq \emptyset \equiv u \in T[C, \quad (6)\]
\[T \subseteq T' \Rightarrow \text{orig}(u,T,C) \subseteq \text{orig}(u,T',C). \quad (7)\]

In the sequel we shall write \(\text{orig}(u,T)\) as short for \(\text{orig}(u,T,B)\).

**Lemma 4** For all traces \(u\) we have
\[\text{orig}(u,T_\omega) = (\bigcap n : n \geq 0 : \text{orig}(u,T_n)).\]

**Proof** We derive
\[\text{orig}(u,T_\omega) \]
\[= \{ \text{definition of } T_\omega \} \]
\[\text{orig}(u,(\bigcap n : n \geq 0 : T_n)) \]
\[= \{ \text{definition of } \text{orig} \} \]
\[\{t : t \in t((\bigcap n : n \geq 0 : T_n)) \land t[B = u : t]\} \]
\[= \{ \text{definition of } \bigcap \} \]
\[\{t : (\forall n : n \geq 0 : t \in T_n) \land t[B = u : t]\} \]
3.1 Projection and Descending Sequences of Processes

\[ \begin{align*}
= & \quad \{ \text{predicate calculus, using } (\exists n : n \geq 0) \} \\
= & \quad \{ \text{definition of } \exists \} \\
= & \quad \{ \text{definition of } \cap \} \\
= & \quad \{ \text{definition of } \text{orig} \} \\
= & \quad \{ \text{definition of } \text{orig}(u, T_n) \}
\end{align*} \]

(End of Proof)

For trace \( u \), process \( T \), and alphabet \( C \), the number \( \text{minorig}(u, T, C) \) is defined by

\[ \text{minorig}(u, T, C) = (\text{MIN } t : t \in \text{orig}(u, T, C) : \ell(t)) \].

Notice that \( \text{minorig}(u, T, C) = \infty \) if and only if \( \text{orig}(u, T, C) = \emptyset \), that is, iff \( u \notin T \left[ C \right] \). Again, we write \( \text{minorig}(u, T) \) for \( \text{minorig}(u, T, B) \). For instance, in Example 0 we have \( \text{minorig}(b, T_n) = \ell(a^n b) = n + 1 \).

For convenience, we define the sequence \( U \) and process \( U_\omega \) by \( U_n = T_n[B] \) and \( U_\omega = (\cap n : n \geq 0 : U_n) \). Thus, (5) expresses that \( T_\omega[B] \subseteq U_\omega \). We also adopt the following convention for naming traces. Traces \( t \) and \( t_i \) belong to trace structures with alphabet \( A \) (like \( T_n \) and \( T_\omega \)), and traces \( u, u_i, \) and \( v \) belong to trace structures with alphabet \( B \) (like \( U_n \) and \( U_\omega \)).

**Theorem 0** Equality holds in (5) if and only if

\[ (\forall u : u \in U_\omega : (\exists K : (\forall n : n \geq 0 : \text{minorig}(u, T_n) \leq K))) \].

**Proof** We show the two implications separately.

**Only if** Assume equality holds in (5), that is, \( T_\omega[B] = U_\omega \). Let \( u \in U_\omega \). Hence, \( u \in T_\omega[B] \). On account of (6), take some \( t \in \text{orig}(u, T_\omega) \). From Lemma 4 we then infer \( (\forall n : n \geq 0 : t \in \text{orig}(u, T_n)) \). Therefore, taking \( K = \ell(t) \) suffices as upper bound. This proves (8).

**If** Assume condition (8) holds. Let \( u \in U_\omega \). On account of assumption (8) let \( K \) be an upper bound of \( \{ n : n \geq 0 : \text{minorig}(u, T_n) \} \). Consider the sequence of trace sets \( S \) defined by

\[ S_n = \{ t : t \in \text{orig}(u, T_n) \land \ell(t) \leq K : t \} \].

Since \( A \setminus B \) is finite, \( \ell(S_n) \leq K + 1 \), and \( S_n[B] = \{ u \} \) is finite, Lemma 1 tells us that each \( S_n \) is finite. Furthermore, this sequence is descending by (7). We now derive
true
= \{ \text{choice of } K \} \\
(\forall n : n \geq 0 : S_n \neq \emptyset) \\
= \{ \text{Lemma 2 using the finiteness of all } S_n \text{ and that } S \text{ is descending} \} \\
(\cap n : n \geq 0 : S_n) \neq \emptyset \\
\Rightarrow \{ S_n \subseteq \text{orig}(u, T_n) \text{ for all } n \} \\
(\cap n : n \geq 0 : \text{orig}(u, T_n)) \neq \emptyset \\
= \{ \text{Lemma 4} \} \\
\text{orig}(u, T_\omega) \neq \emptyset \\
= \{ (6) \} \\
\Rightarrow u \in T_\omega[B]

This proves equality in (5).

(End of Proof)

The following example shows that (8) is not a sufficient condition for equality in (5) if \( A \setminus B \) is allowed to be infinite.

Example 3  Take \( A = \{ i : i \geq 0 : a_i \} \cup \{ b \} \), define the sequence \( T \) by

\( T_n = \langle A, \text{pref}\{ i : i \geq n : a_i ; b \} \rangle \)

and take \( B = \{ b \} \). Then we have:

\[ T_\omega = \langle A, \{ \epsilon \} \rangle \]
\[ T_\omega[B] = \langle B, \{ \epsilon \} \rangle \]
\[ T_n[B] = \langle B, \{ \epsilon, b \} \rangle \text{ for } n \geq 0 \]
\[ U_\omega = \langle B, \{ \epsilon, b \} \rangle \]

Thus, \( T_\omega[B] \neq U_\omega \), but (8) is satisfied, because we also have:

\[ \text{minorig}(\epsilon, T_n) = 0, \]
\[ \text{minorig}(b, T_n) = \ell(a_n b) = 2. \]

Notice that \( \text{orig}(b, T_n) \) is infinite for every \( n \geq 0 \).

(End of Example)

Theorem 1  Equality holds in (5) if
3.1 Projection and Descending Sequences of Processes

\[(\forall u :: (\exists n : n \geq 0 : \#\text{orig}(u,T_n) < \infty))\]. \hspace{1cm} (9)

**Proof** We show that (9) implies (8), and apply Theorem 8. Assume (9). Let \(u\) be a trace in \(U_\omega\). On account of (9) let \(i, i \geq 0,\) be such that \(\#\text{orig}(u,T_i) < \infty\). Now define \(K\) as \((\text{MAX } t : t \in \text{orig}(u,T_i) : \ell(t))\). Because the sequence \(S\) defined by \(S_n = \text{orig}(u,T_n)\) is descending, this \(K\) suffices as upper bound in (8).

(End of Proof)

**Example 4** That (9) is not a necessary condition for equality in (5), follows from the constant sequence \(T\) defined by

\[T_n = (\{a,b\}, \{i : i \geq 0 : a^i\})\]

with \(B = \{b\}\). This sequence does not satisfy (9), but, of course, we do have equality in (5).

(End of Example)

Before we strengthen (9) we introduce another auxiliary concept. We say "process \(T\) diverges when projected on alphabet \(C\)", denoted by \(\text{div}(T,C)\), when

\[(\exists u :: \#\text{orig}(u,T,C) = \infty)\].

If \(aT \setminus C\) is finite, then \(\text{div}(T,C)\) is equivalent to \(\text{livelockfree}(aT \setminus C,T)\) as defined in [5, Ch. 5]. In case \(aT \setminus C\) is infinite, this equivalence does not hold as is shown by projection of process \(T_0\) on alphabet \(B\) from Example 3.

From (7) we infer

\[T \subseteq T' \land \text{div}(T,C) \Rightarrow \text{div}(T',C).\] \hspace{1cm} (10)

We write \(\text{div}(T)\) as short for \(\text{div}(T,B)\).

**Theorem 2** Equality holds in (5) if

\[(\exists n : n \geq 0 : \neg\text{div}(T_n))\]. \hspace{1cm} (11)

**Proof** We show that (11) implies (9), and apply Theorem 9:

\[(\exists n : n \geq 0 : \neg\text{div}(T_n))\]

\[= \{\text{definition of div}\}\]

\[(\exists n : n \geq 0 : (\forall u :: \#\text{orig}(u,T_n) < \infty))\]
\[ \Rightarrow \{ \text{predicate calculus} \} \]
\[(\forall u : (\exists n : n \geq 0 : \#\text{orig}(u, T_n) < \infty)) \]

(End of Proof)

That (11) is strictly stronger than (9) follows from

Example 5 Define sequence \( T_n \) by
\[ T_n = \{a, b\}, \text{pref}\{i, j : i \geq n \land j \geq 0 : b^i a^j\} \]
and take \( B = \{b\}. \) This sequence satisfies (9), because for \( n = \ell(u) + 1 \) we have \#\text{orig}(u, T_n) \leq 1. \) But it does not satisfy (11), since every \( T_n \) diverges when projected on \( B. \) Notice however that
\[ T_\omega = \{a, b\}, \{i : i \geq 0 : b^i\}, \]
hence, \( T_\omega \) does not diverge when projected on \( B. \) This inspired Theorem 3 below.

(End of Example)

Property 6 For trace \( u, \) process \( T, \) and alphabet \( C, \) the trace set
\[ (\bigcup v : v \leq u : \text{orig}(v, T, C)) \]
equals the trace set
\[ \{ t : t \in T \land (\exists v : v \leq u : t[C = v]) : t \} \]
and it is prefix-closed.

Proof We derive
\[ t \in (\bigcup v : v \leq u : \text{orig}(v, T, C)) \]
\[ = \{ \text{definition of } \bigcup \text{ and } \text{orig} \} \]
\[ (\exists v : v \leq u : t \in T \land t[C = v]) \]
\[ = \{ \text{predicate calculus} \} \]
\[ t \in T \land (\exists v : v \leq u : t[C = v]) \]
and
\[ st \in T \land (\exists v : v \leq u : st[C = v]) \]
\[ = \{ \text{property of projection} \} \]
3.1 Projection and Descending Sequences of Processes

\[ st \in T \land (\exists v_0, v_1 : v_0 \leq v_1 \land s[C = v_0 \land t[C = v_1]) \]
\[ \Rightarrow \{ \text{ tT is prefix-closed, transitivity of } \leq, \text{ and pred. calc. } \} \]
\[ s \in T \land (\exists v_0 : v_0 \leq v : s[C = v_0) \]

(End of Proof)

**Theorem 3**

Equality holds in (5) if \( \neg \text{div}(T) \).

**Proof** We show that \( \neg \text{div}(T) \) implies (9) in order to apply Theorem 1.

Given a trace \( u \), define the sequence of trace sets \( S \) and process \( S \) by

\[
S_n = (\bigcup v : v \leq u : \text{orig}(v, T_n))
\]

\[
S_\omega = (\bigcup v : v \leq u : \text{orig}(v, T_\omega))
\]

From Property 6 we know that these trace sets are prefix-closed. Analogous to Lemma 4, using Property 6, one can prove

\[
S_\omega = (\bigcap n : n \geq 0 : S_n).
\]

Furthermore, \( S^{[k]}_n \) is bounded and \( S^{[k]}_n[B = \text{pref} \{ u \} \) is finite. Hence, by Lemma 1 all \( S^{[k]}_n \) are finite. We now derive

\[
\neg \text{div}(T)
\]

\[
= \{ \text{ definition of div } \}
\]

\[
(\forall u :: \# \text{orig}(v, T_\omega) < \infty)
\]

\[
= \{ \text{ a trace has a finite number of prefixes, and set theory } \}
\]

\[
(\forall u :: \#(\bigcup v : v \leq u : \text{orig}(v, T_\omega)) < \infty)
\]

\[
= \{ \text{ definition of } S_\omega \}
\]

\[
(\forall u :: S_\omega < \infty)
\]

\[
= \{ (12) \}
\]

\[
(\forall u :: \#(\bigcap n : n \geq 0 : S_n) < \infty)
\]

\[
= \{ \text{ Lemma 3, using that } S \text{ is a descending sequence of level-finite prefix-closed trace sets } \}
\]

\[
(\forall u :: (\exists n : n \geq 0 : \#S_n < \infty))
\]

\[
= \{ \text{ definition of } S_n \}
\]

\[
(\forall u :: (\exists n : n \geq 0 : \#(\bigcup v : v \leq u : \text{orig}(v, T_n)) < \infty))
\]

\[
= \{ \text{ set theory, (6), and } T \text{ is descending } \}
\]

\[
(\forall u :: (\exists n : n \geq 0 : \#\text{orig}(u, T_n) < \infty))
\]
(End of Proof)

By the way, notice that we proved equivalence of (9) and $-\text{div}(T_\omega)$ instead of just the desired implication. Let us summarize the relationships between the various conditions for equality in (5) as expressed by the theorems of this section. Keep in mind that finiteness of $A \setminus B$ is a global assumption.

$$(\exists n : n \geq 0 : -\text{div}(T_n))$$

$$\Rightarrow \{ (10), \text{using } T_\omega \subseteq T_n \text{ for all } n \}$$

$$-\text{div}(T_\omega) = \{ \text{proof of Theorem 3 } \}$$

$$= \{ \forall u : u \in U_\omega : (\exists n : n \geq 0 : \#\text{orig}(u, T_n) < \infty) \}$$

$$\Rightarrow \{ \text{proof of Theorem 1 } \}$$

$$= \{ \forall u : u \in U_\omega : \#\{ n : n \geq 0 : \text{minorig}(u, T_n) \} < \infty \}$$

$$= \{ \text{Theorem 0 } \}$$

$$T_\omega \setminus B = U_\omega$$

Theorem 3 can also be interpreted as expressing that projection on alphabet $B$ is downward continuous “in” processes that do not diverge when projected on $B$. An alternative proof of this can be based on a slightly different version of projection as used in the mathematical model for CSP [2, Section 2.8]. For process $T$ and alphabet $B$ the process $T[B]$ is defined by

$$a(T[B]) = aT \cap B$$

$$t(T[B]) = \{ t : t \in T : t[B] \cup \{ u, v : \#\text{orig}(u, T) = \infty \wedge v \in B^* : uv \} \}$$

Obviously, $T[B] \subseteq T[B]$ and if $-\text{div}(T)$ then $T[B] = T[B]$. Furthermore, it is known that $-\text{projection is downward continuous. Hence, we can derive}$

$$(\bigcap n : n \geq 0 : T_n[B])$$

$$\subseteq \{ T_n[B] \subseteq T_n[B] \}$$

$$(\bigcap n : n \geq 0 : T_n[B]) = \{ -\text{projection is downward continuous } \}$$

$$(\bigcap n : n \geq 0 : T_n)[B] = \{ \text{definition of } T_\omega \}$$

$$T_\omega[B]$$
proving Theorem 3.

Finally, we note that some of the conditions can be weakened. For instance, finiteness of \( A \setminus B \) can be replaced by "finite fanout on \( A \setminus B \)." The condition of Theorem 3, i.e. \( \neg \text{div}(T_\omega) \), can be weakened to

\[
(\forall u : \#(\text{orig}(u, T_\omega) \cap \{t, a : a \in \Omega \land ta \in T_\omega : ta\}) < \infty).
\]

3.2 Application

In this subsection we give a condition under which the greatest fixed point of equation (1) is obtained as the limit of the approximations starting from the top element.

Property 7  Let \( T \) and \( U \) be processes such that \( aT \subseteq aU \), and let \( C \) be an alphabet such that \( \neg \text{div}(U, C) \). Then we have \( \neg \text{div}(U \wedge T, C) \).

Proof  Observe that \( U \wedge T \subseteq U \), and apply (10).
(End of Proof)

Let \( A \) be a finite alphabet, \( p \) a renaming of \( A \), and \( R \) a process in \( T(A \cup p \cdot A) \). The function \( f : T(A) \to T(A) \) is defined by

\[
f(S) = (R \wedge p \cdot S)[A].
\]

Property 8  If \( S \in T(A) \) is a fixed point of the function \( f \), then \( S \) is at most

\[
(\bigcap n : n \geq 0 : f^n(RUN(A))).
\]  \hspace{1cm} (13)

Proof  Since \( RUN(A) \) is the top of \( T(A) \) we have for any fixed point \( S \) of \( f \) that \( S \subseteq RUN(A) \). From the monotonicity of \( f \) then follows that for all \( n \geq 0 \) we have

\[
S = f^n(S) \subseteq f^n(RUN(A)).
\]

Thus, \( S \subseteq (\bigcap n : n \geq 0 : f^n(RUN(A))) \).
(End of Proof)

Theorem 4  If \( \neg \text{div}(R, A) \) holds, then the greatest fixed point of the function \( f \) is given by (13).
Proof. On account of Property 8 it is sufficient to show that (13) is a fixed point of $f$. We derive

\[
f(\bigcap n : n \geq 0 : f^n(\text{RUN}(A)))
\]
\[
= \quad \{ \text{definition of } f \}\ 
(U \wp p \cdot (\bigcap n : n \geq 0 : f^n(\text{RUN}(A))))[A]
\]
\[
= \quad \{ \text{weaving and renaming are downward continuous} \}
(\bigcap n : n \geq 0 : U \wp p \cdot f^n(\text{RUN}(A)))[A]
\]
\[
\vdash \quad \{ \text{Theorem 2 using Property 7 and } \neg \text{div}(R, A) \}
(\bigcap n : n \geq 0 : (U \wp p \cdot f^n(\text{RUN}(A)))[A]
\]
\[
= \quad \{ \text{definition of } f \}
(\bigcap n : n \geq 0 : f^{n+1}(\text{RUN}(A)))
\]
\[
= \quad \{ f \text{ is monotonic} \}
(\bigcap n : n \geq 0 : f^n(\text{RUN}(A)))
\]

(End of Proof)

Example 6. The condition $\neg \text{div}(R, A)$ is not a necessary condition in Theorem 4. That is, (13) can be the greatest fixed point even if the condition is not satisfied. Take, for instance, $A = \{a\}$ and

\[
R = \text{PR}((p \cdot a)^*; a^*)
\]

In this case we have

\[
f(\text{STOP}(A)) = \text{RUN}(A) = f(\text{RUN}(A)).
\]

Thus, (13) equals $\text{RUN}(A)$, which is the unique fixed point of $f$.

(End of Example)

The preceding theorem can be generalised to

Theorem 5. If $\neg \text{div}(R, A)$ holds, then for any process $T$ in $T(A)$

\[
(\bigcap n : n \geq 0 : (\bigcup m : m \geq n : f^m(T)))
\]

is a fixed point of the function $f$.

Proof. Define the sequence $U$ by

\[
U_n = R \wp p \cdot (\bigcup m : m \geq n : f^m(T)).
\]
This sequence is descending and from Property 7 using \( \neg \text{div}(R, A) \) we infer \( \neg \text{div}(U_n, A) \). We now derive

\[
f(\bigcap n : n \geq 0 : (\bigcup m : m \geq n : f^m(T)))
= \{ \text{definition of } f \}

(End of Proof)

4 The CMS Approach

In Subsection 4.0 we define a distance function for processes and show that it is a metric. The resulting metric space is proven to be complete and compact. The relationship with the partial order of the preceding section is briefly discussed. Subsection 4.1 applies this to equation (1). We give a condition under which the associated function is a contraction on the metric space. This yields an approximation theorem for solutions of equation (1).

In this section \( A \) is an alphabet.
4.0 The Metric

For $T \in T(A)$ and $U \in T(A)$ we define the distance $d(T,U)$ between $T$ and $U$ by

$$d(T,U) = 2^{-\left(\text{MIN}_{t \in tT \uplus tU} \ell(t)\right)},$$

where $X \uplus Y$ denotes the symmetric difference of sets $X$ and $Y$; that is, $X \setminus Y \cup Y \setminus X$. This notion of distance is similar to the Golson distance defined in [3] for synchronization trees.

Before we show that $d$ is a metric on $T(A)$, it is useful to have another characterization of the distance between two processes. For process $T$ and natural number $k$, the $k$-th approximation of $T$ is the process denoted by $T^{(k)}$ and defined by

$$T^{(k)} = \{aT, \{t : t \in T \land \ell(t) \leq k : t\}\}.$$

The process $T^{(k)}$ is also called a finite approximation of $T$. For example, we have $T^{(0)} = \text{STOP}(aT)$. Furthermore, process $T$ is the least upper bound (in the sense of the preceding section) of its finite approximations, that is,

$$T = (\bigcup k : k \geq 0 : T^{(k)}).$$

**Property 9** For processes $T$ and $U$ in $T(A)$ we have

$$(\text{MIN}_{t \in tT \uplus tU} \ell(t)) = (\text{MIN} k : T^{(k)} \neq U^{(k)} : k).$$

From the prefix-closedness of $k$-th approximations then follows that for any natural number $k$

$$d(T,U) < 2^{-k} \iff T^{(k)} = U^{(k)}.$$

**Theorem 6** $(T(A),d)$ is a metric space.

**Proof** Axioms 0, 1, and 2 for a metric (cf. Section 1.1) are trivially satisfied. We now prove Axiom 3 (triangle inequality). Let $T$, $U$, and $V$ be processes in $T(A)$. We have to show $d(T,U) \leq d(T,V) + d(V,U)$. Without loss of generality we assume $T \neq U$. On account of this let $k$ be the smallest natural number such that $T^{(k)} \neq U^{(k)}$; hence, we have $d(T,U) = 2^{-k}$. We now derive

$$\text{true}$$

$$= \{ \text{calculus} \}$$
4.0 The Metric

\[ T^{(k)} = V^{(k)} \lor T^{(k)} \neq V^{(k)} \]
\[ \Rightarrow \quad \{ T^{(k)} \neq U^{(k)} \} \]
\[ V^{(k)} \neq U^{(k)} \lor T^{(k)} \neq V^{(k)} \]
\[ \Rightarrow \quad \{ \text{Property 9} \} \]
\[ d(V, U) \geq 2^{-k} \lor d(T, V) \geq 2^{-k} \]
\[ = \quad \{ d(T, U) = 2^{-k} \text{ and Axiom 0 for a metric} \} \]
\[ d(T, U) \leq d(T, V) + d(V, U) \]

(End of Proof)

Theorem 7 \( \langle T(A), d \rangle \) is a CMS.

Proof We show that every Cauchy sequence has a limit in \( T(A) \). Let \( T \) be a Cauchy sequence in \( T(A) \). Define the sequence \( U \) and process \( L \) by

\[ U_i = (\cup j : j \geq i : T_j) \quad \text{for } i \geq 0, \text{ and} \]
\[ L = (\cap i : i \geq 0 : U_i). \]

Obviously, the processes \( U_i \) are in \( T(A) \), and hence so is \( L \). We show that \( L \) is the limit of sequence \( T \) by showing that for any natural number \( k \) there exists a natural number \( N \) such that for all natural \( n, n \geq N \), we have \( d(L, T_n) < 2^{-k} \).

Let \( k \) be a natural number and let natural number \( N \) be such that \( d(T_m, T_n) < 2^{-k} \) for all \( m \) and \( n \) at least \( N \). Such an \( N \) exists, since \( T \) is a Cauchy sequence. We show for \( n \geq N \) that \( L^{(k)} = T_n^{(k)} \), which then implies \( d(L, T_n) < 2^{-k} \) on account of Property 9. From the choice of \( N \) together with Property 9 we infer

\[ (\forall m, n : m \geq N \land n \geq N : T_m^{(k)} = T_n^{(k)}). \quad (15) \]

Now we derive for any \( n \geq N \)

\[ L^{(k)} \]
\[ = \quad \{ \text{definition of } L \text{ and property of } k\text{-th approximation} \} \]
\[ (\cap i : i \geq 0 : U_i^{(k)}) \]
\[ = \quad \{ U_i \text{ is a descending sequence of processes} \} \]
\[ (\cap i : i \geq N : U_i^{(k)}) \]
\[ = \quad \{ \text{definition of } U_i \text{ and property of } k\text{-th approximation} \} \]

\[ (\forall m, n : m \geq N \land n \geq N : T_m^{(k)} = T_n^{(k)}). \quad (15) \]
\[(\cap i : i \geq N : (\bigcup j : j \geq i : T_j^{(k)}))\]
\[=\{ (15) \}\]
\[(\cap i : i \geq N : (\bigcup j : j \geq i : T_n^{(k)}))\]
\[=\{ \text{intersection and union are idempotent} \}
\]

(End of Proof)

Although not strictly necessary for our current analysis, we also know something about the compactness of our metric space. A metric space is compact when every sequence in it has a converging subsequence. Sequence \(S\) is a subsequence of sequence \(T\) when there exists a monotonic one-to-one mapping \(g\) of the set of natural numbers into itself such that \(T \circ g = S\).

**Theorem 8** If alphabet \(A\) is finite then \(\langle T(A), d \rangle\) is compact.

**Proof** Assume \(A\) is finite and let \(T\) be a sequence in \(T(A)\). We first define a sequence \(U\) of subsequences of \(T\). Sequence \(U(0)\) is just \(T\), and for \(k \geq 1\) we obtain \(U(k)\) as a subsequence of \(U(k - 1)\) for which the \(k\)-th approximations of the processes are all equal. This is possible because there exist only a finite number of sets of traces over \(A\) of length at most \(k\) (\(A\) being finite). Now define the sequence \(V\) by \(V_n = U(n)_n\). Then \(V\) is a subsequence of \(T\) and it is a Cauchy sequence; hence, it converges by Theorem 7.

(End of Proof)

**Example 7** When \(A\) is infinite, \(\langle T(A), d \rangle\) is not compact. Consider the infinite alphabet \(A = \{i : i \geq 0 : a_i\}\) and the sequence \(T\) in \(T(A)\) defined by

\[T_n = \langle A, \{i : i \leq n : a_i\} \rangle.\]

This sequence has no converging subsequence since

\[m \neq n \Rightarrow d(T_m, T_n) = \frac{1}{2},\]

for all natural numbers \(m\) and \(n\).

(End of Example)

For finite alphabet \(A\) we can also express the following relationship between the partial order as defined in Section 3 and the metric. If \(T\) is an
ascending or descending sequence in \( \langle T(A), \subseteq \rangle \) then it is a converging sequence in \( \langle T(A), d \rangle \) and its least upper bound in \( \langle T(A), \subseteq \rangle \) equals its limit in \( \langle T(A), d \rangle \). The ascending sequence defined in Example 7 shows that this is not necessarily the case when \( A \) is infinite. By the way, notice the similarity of (14) and the definition of process \( L \) in terms of the sequence \( T \) in the proof of Theorem 7.

4.1 Application

In [9, Prop. 3.3 combined with Thm. 3.8] a condition is given under which equation (1) has a unique solution. We now strengthen this result in Theorem 10, yielding an alternative proof for the earlier result.

Let \( A \) be an alphabet, \( p \) a renaming of \( A \), and \( R \) a process in \( T(A \cup p \cdot A) \). The function \( f : T(A) \rightarrow T(A) \) is defined by

\[ f(S) = (R \leftarrow p \cdot S)[A]. \]

**Theorem 9** The function \( f \) is a contraction on \( \langle T(A), d \rangle \) if

\[ (\forall r : r \in R : \ell(r[p \cdot A]) \leq \ell(r[A])). \]  

(16)

**Proof** Let \( T \) and \( U \) be processes in \( T(A) \). We show that \( f \) is a contraction by proving

\[ d(f(T), f(U)) \leq \frac{1}{2} d(T, U). \]

Without loss of generality we may assume \( T \neq U \). On account of this, let \( k \) be such that \( d(T, U) = 2^{-k} \).

For any \( S \in T(A) \) we have

\[ f(S) = \{ r : r \in R \land r[p \cdot A] \in p \cdot S : r[A] \}. \]

Hence, for any trace \( s \) of length \( l \) in \( f(S) \) there exists a trace \( r \in R \) with \( r[A] = s \), \( \ell(r[A]) = l \), and, due to (16), \( \ell(r[p \cdot A]) \leq l \). If \( r \) is of the form \( r'[p \cdot a] \), for some \( a \in A \), then \( r' \in R \) since \( R \) is prefix-closed, \( r'[p \cdot A] \in p \cdot S \) since \( S \) is prefix-closed, and \( r'[A] = s \). Moreover, \( \ell(r'[p \cdot A]) \leq l - 1 \). If on the other hand \( r \) ends in a symbol of \( A \) then \( \ell(r[p \cdot A]) \leq l - 1 \) on account of (16) and the fact that \( R \) is prefix-closed. In any case, we conclude for any trace \( s \)

\[ s \in f(S) \iff s = s \vee (\exists r : r \in R \land r[A] = s : r[p \cdot A] \in p \cdot S^{[\ell(s) - 1]}) \]  

(17)

Now we show that \( f(T)^{(k)} = f(U)^{(k)} \), which then implies

\[ d(f(T), f(U)) \leq 2^{-k} = \frac{1}{2} d(T, U). \]

For \( s \in A^* \) such that \( \ell(s) \leq k \) we derive

\[ d(f(T), f(U)) \leq 2^{-k} = \frac{1}{2} d(T, U). \]
\begin{align*}
  & s \in f(T) \\
  & = \{ (17) \} \\
  & s = \varepsilon \lor (\exists r : r \in R \land rA = s : r[p \cdot A \in p \cdot T(\ell(s)-1)]) \\
  & = \{ \ell(s) \leq k \text{ and } T^{(k-1)} = U^{(k-1)} \text{ because } d(T, U) = 2^{-k} \} \\
  & s = \varepsilon \lor (\exists r : r \in R \land rA = s : r[p \cdot A \in p \cdot U(\ell(s)-1)]) \\
  & = \{ (17) \} \\
  & s \in f(U)
\end{align*}

(End of Proof)

**Example 8**  Condition (16) is not necessary for \( f \) to be a contraction. Consider the case \( A = \{a\} \) and \( R = PR(a | p \cdot a) \). Then \( R \) does not satisfy (16), since \( p \cdot a \in R \). Nevertheless, for any \( T \in T(A) \) we have \( f(T) = PR(a) \), and therefore \( f \) is a contraction.

(End of Example)

**Theorem 10**  If the function \( f \) is a contraction then it has a unique fixed point and this fixed point \( U \) is for every \( T \in T(A) \) the limit of the sequence \( S \) defined by

\[ S_n = f^n(T). \]

Furthermore, we have for all \( n \geq 0 \)

\[ s^{(n)} = u^{(n)}, \]

that is, the rate of convergence of \( S \) is at least "linear".

**Proof**  The first two claims follow from Banach's Contraction Theorem, using the completeness of our metric space. Furthermore, we observe that

\begin{align*}
  & d(S_n, U) \\
  & = \{ \text{definition of } S_n \text{ and } U \text{ is fixed point of } f \} \\
  & d(f^n(T), f^n(U)) \\
  & \leq \{ f \text{ contracts by at least a factor } \frac{1}{2} \} \\
  & 2^{-n}d(T, U) \\
  & < \{ d(T, U) < 1 \} \\
  & 2^{-n}
\end{align*}
and, hence, $S^{(n)}_A = U^{(n)}$ follows from Property 9.

(End of Proof)

By the way, it is possible that $f$ has a unique fixed point but that $f$ is not a contraction for our metric on $T(A)$. One need only look back to Examples 1 and 2. The functions exhibited there have a unique fixed point, but that fixed point is not the limit of the approximations obtained by iterating the function on $RUN(A)$ (recall the relationship between the metric and the partial order mentioned at the end of the preceding subsection). Hence, these functions cannot be contractions. This does not necessarily mean that they cannot be contractions for some other metric on $T(A)$.

A slightly different approach to proving Theorem 9 can be taken by extending the notion of a contraction to functions from one metric space into another. Let $(D_0, d_0)$ and $(D_1, d_1)$ be metric spaces and let $X$ be a subset of $D_0$. The function $f: D_0 \to D_1$ is called a $c$-contraction on $X$, where $c$ is a real number, when

$$d_1(f(x), f(y)) \leq c \cdot d_0(x, y)$$

for all $x$ and $y$ in $X$. For instance, renaming is a 1-contraction on the whole space, and so is weaving with a fixed process. If $f_1: D_0 \to D_1$ is a $c_0$-contraction on $X$, $X \subseteq D_0$, and $f_1: D_1 \to D_2$ is a $c_1$-contraction on $f_1(X)$, then $f_1 \circ f_0$ is a $c_0 \cdot c_1$-contraction on $X$. The problem in Theorem 9 now is to show that the involved projection is a $\frac{1}{2}$-contraction on the image space created by the composition of renaming and weaving. So, again, projection is the problematic operator.

5 Concluding Remarks

The introduction of recursive components in the program notation of Trace Theory gives rise to a recursive equation involving non-empty prefix-closed trace sets. It becomes, therefore, interesting to know more about the solutions of this equation. For instance, when does the equation have a solution, and if there is more than one solution how can a canonical solution be selected? From the use of a partial order on the process domain (based on trace set inclusion) it is known that the equation has a least and a greatest solution (with respect to this order). Furthermore, the least solution can be approximated by iteration.
In the context of this partial order we have carefully analyzed the projection operator and we have given a number of conditions under which projection distributes over the greatest lower bound of descending sequences of processes (Theorems 0 through 3). Application of this has provided a condition under which the greatest solution of our equation can be approximated by iteration (Theorem 4). It has also been shown that iteration starting anywhere converges to a solution under this condition (Theorem 5).

We have introduced a metric on the process domain and we have shown that it yields a compact complete metric space (Theorems 6 through 8). Under a condition formulated previously the function derived from our equation turned out to be a contraction (Theorem 9). By applying Banach's Contraction Theorem we then showed that under this condition our equation has a unique solution that can be approximated by iteration starting anywhere, and that the rate of convergence is at least linear (Theorem 10).

The conditions that we have formulated are sufficient for their respective purposes but not necessary, as we have shown by appropriate examples. We are still interested in conditions that are sufficient and necessary. That is, exactly when can the greatest solution be approximated, exactly when is the function a contraction, and exactly when has the equation a unique solution?

We have used only one particular partial order and metric in our analysis of the equation. There is no reason to restrict oneself to these choices. It is very well possible that other partial orders and metrics bring new insights. For example, one could think of a metric that not only indicates in which smallest finite approximation two processes differ, but also by how much they differ. A careful analysis of the contracting properties of projection seems a promising area for further investigation.
